Britain’s alcohol duty overhaul nudged drinkers toward lower-strength products

An official evaluation found that prices shifted as intended, with stronger drinks costing more and some producers cutting ABV to secure lower rates

Thursday, October 29, 2026

Britain’s alcohol duty overhaul has started to shift parts of the drinks market toward lower-strength products, according to an official evaluation from HM Revenue & Customs and HM Treasury, which said the tax changes also kept government revenue broadly stable while simplifying the system for producers and sellers.

The report said prices moved largely as policymakers intended after duty rates were tied more closely to alcohol content. Higher-strength drinks became relatively more expensive, while lower-strength products were cheaper or saw little change. Officials also found signs that some consumers switched toward lower-strength options, especially in beer and cider, and that some producers reduced the alcohol content of products to qualify for lower duty.

The evaluation looked at the effects of the reform using HMRC administrative records, commercial sales data, surveys on alcohol consumption, and consumer research gathered after the new system took effect. The government had said the changes were meant to replace a more complicated structure based on product categories and volume with a clearer approach that taxes alcohol more directly by strength, measured as alcohol by volume, or ABV.

According to the report, the earlier system had become difficult to navigate and did not reflect alcohol strength in a consistent way across beer, cider, wine, and spirits. The new framework was designed to make tax treatment more uniform across those categories, while also supporting health policy goals and limiting pressure on public revenue.

The findings suggest the new duty structure has had some influence on industry behavior. Producers in parts of the market appear to have adjusted recipes or product specifications to lower ABV and move into more favorable tax positions. That carries practical implications for brewers, cider makers, winemakers, and spirits companies that are weighing whether reformulation can improve margins or help them respond to changing consumer demand. It also offers new evidence for drinks businesses trying to judge whether lower-strength products can be commercially viable under a tax system that rewards reduced alcohol content.

The report was more cautious on other policy goals. While officials said the changes have better aligned taxation with alcohol strength, the evaluation did not allow them to confirm broader benefits such as lower prices in pubs or measurable reductions in alcohol-related harm. That leaves an important open question for the drinks trade and the hospitality sector, which have a strong interest in whether tax incentives for lower-strength products can support pubs and other on-trade venues as well as public health aims.

For consumers, the main effect identified by the study was a relative price shift rather than a broad drop in alcohol prices. The report said stronger products generally became more expensive compared with weaker ones, reflecting the government's effort to link tax more directly to the amount of alcohol in a drink. The evidence of substitution toward lower-strength drinks was described as limited but noticeable in some categories, with beer and cider standing out more than others.

For the government, one of the central findings was that revenue did not appear to be undermined by the change. Duty receipts remained broadly stable, the report said, suggesting the Treasury was able to protect tax income even as the structure of the system changed. That point is likely to matter in future debates over alcohol taxation, since ministers have long had to balance health policy objectives against the need to preserve a dependable source of revenue.

The evaluation also said the new model reduced administrative burdens and improved transparency. A tax system that is more directly tied to alcohol content may be easier for businesses to understand and for officials to explain, especially when compared with a framework built around multiple product categories and separate bandings. That could be significant for producers with broad portfolios that cross several types of drinks, as well as for smaller companies that face proportionally higher compliance costs.

In the ministerial foreword, the government described alcohol duty as both a revenue tool and a public health instrument. The report's findings do not settle the debate over how much taxation can change drinking behavior or improve health outcomes, but they do indicate that producers and consumers respond when tax rates move more clearly

with product strength.

The government said continued monitoring will be needed to measure the longer-term effects on consumption, health outcomes, and revenue. For now, the official assessment points to a reform that changed pricing signals in the market, prompted some product reformulation, and gave drinks companies a stronger financial reason to develop and sell lower-strength options.
